

chitin formation and diagenesis pdf

There are several books on properties of chitin and associated biomolecules and their biochemical significance. However, the present volume, "Chitin: Formation and Diagenesis"™ deals with a wide variety of biogeochemical and organic geochemical aspects of this vital macromolecule written by leading authors and experts in the field.

Chitin: Formation and Diagenesis (Topics in Geobiology

Each chapter is carefully peer reviewed and is an updated account of recent research in isotopic, nanostructural, biochemical, microstructural, geochemical, paleontological and experimental aspects of chitin formation, distribution and preservation in the environment and earth history.

Chitin is a polymer of N-acetyl glucosamine that forms the protective exoskeleton of all arthropods and is replaced periodically during growth and development. Chitin biosynthesis starts with the disaccharide trehalose, culminating in the polymerization of the N-acetyl glucosamine subunits by chitin synthase to produce chitin microfibrils.

Chitin, a biopolymer of N-acetylglucosamine, is abundant in invertebrates and fungi, and is an important structural molecule. There has been a longstanding belief that vertebrates do not produce chitin, however, we have obtained compelling evidence to the contrary.

Chitin is endogenously produced in vertebrates

Chitin and Chitosan Processing Chitin and chitosan are natural resources waiting for a market. They were waste products of the crabs and shrimp canning industry. The US Department of Commerce reported in 1973 that they were over 1,50,000 Mt of chitin produced as processing waste from shellfish, krill, clams, oysters, squid, and fungi.

Chitin is used in industry in many processes. Examples of the potential uses of chemically modified chitin in food processing include the formation of edible films and as an additive to thicken and stabilize foods. Processes to size and strengthen paper employ chitin and chitosan. Research
